

Looking to build a mobile application for Android and iOS.

Number of screens: this is a question I was asked. There are maybe 15 truly different screens, but 30 overall (depends if we consider the same layout with different title a different page or not)

Design: provided, will need more information here as to what dimensions are needed

Technical implementation:

- Server:
 - Integrate with Facebook services (facebook login, request to manage accounts)
 - Integrate with server API (provided) - REST API
 - Integrate with Google location services
- Native integration
 - Location services
 - Upload photos

The app aims to provide a way to create and organise events. Photos will be uploaded from device to server using provided services.

The process:

- Use trello (or JIRA if you consider it's better)
- Git for version control
- Slack for communication

If you would like to know more information an NDA must be signed between parties.
